Slide 69

Principal Components Analysis (PCA)

- Rotates the data in species space so that major part of the variation is shown on the first axes.
- Linear representation of the data: usually inadequate for community analysis but good for reducing environmental measurements.

Why ordination?

- Nobody should want to make ordination, but they are desperate with multivariate data.
- Show as much as possible with only a few axes, and explain those dimensions.

Slide 71

Rotation in species space

- 1. Move the axis origin to the centroid of the species space (species averages)
- 2. Rotate the axes so that the first axis ⁵ becomes
 - (a) As close to all observations as possible, which means that it
 - (b) Explains as much of the variance as possible.
- First rotated axes show the configuration as well as possible.

Major ordination methods

Slide 73

How computer sees the configuration?

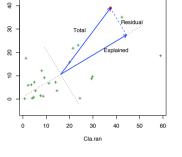

The configuration of points in species space can be defined either

- 1. As distances s_i, s_k and angles θ_{ik} from the origin.
 - Both included in covariances and variances.
 - $\cos \theta$ is Pearson's correlation coefficient.
- 2. As Euclidean distances d_{ik} between pairs of points.

Explaining the variation

- Total variation: Sum of squared distances from the origin.
- Explained variation: Sum of squared projections onto principal components = λ .
- Residual variation: Sum of squared orthogonal distances from the principal components.
- Only a rotation: All min(S, N)axes explain everything.

©2002-2004 Jari Oksanen

Vegetation Analysis

Major ordination methods

Slide 74

Singular Value Decomposition (SVD)

$$x_{ij}^{(M)} = \bar{x}_j + \sum_{m=1}^{M} v_{im} \lambda_m^{1/2} u_{jm}$$

- An M-order least squares approximation of data matrix as a product of orthonormal loading matrices for sites v_{im} and species u_{im} and corresponding eigenvalue λ_m
- Zero-order approximation: All species at their average abundace at the origin.
- When $M = \min(S, N)$ then approximation exact and $\sum \lambda =$ total variance.
- A numerical way of saying that PCA is only a rotation.

©2002-2004 Jari Oksanen Dept. Biology, Univ. Oulu, Finland February 17, 2004

©2002-2004 Jari Oksanen

Dept. Biology, Univ. Oulu, Finland

Major ordination methods Slide 75

Loadings and scores

• Matrices **V** and **U** are orthonormal in SVD.

- Average is zero

 $\sum_{i} u_{im} = 0$

Sum of squares is one

 $\sum_{i} u_{im}^2 = 1$

- Components are uncorrelated

 $\sum_{i} u_{im} = 1$ $\sum_{i} u_{im} u_{in} = 0; \forall m \neq n$

- Normal scaling in PCA:
 - Singular values σ are scaled to covariance eigenvalues $\lambda = \sigma^2/(n-1)$.
 - Species loadings v_{jm} kept orthonormal: Rotation matrix.
 - Site scores scaled by singular values $\sigma_m^2 u_{im}$: Reflect the importance of axes and show the real configuration.
 - Sum of squares of scaled site scores = $\lambda_m(n-1)$.

Dept. Biology, Univ. Oulu, Finland

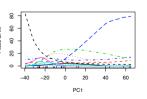

February 17, 2004

Vegetation Analysis Major ordination methods Slide 77

Linear response model

- PCA assumes that species have a linear regression with PCs.
- Loading is the regression coefficient between PC and the species.
- PCA may "fail": Real species responses rather unimodal despite PCA assumptions.

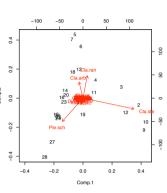

Vegetation Analysis Major ordination methods

Biplot: Graphical SVD

- Species loadings and site scores in the same plot: Graphical order 2 approximation of the data.
- Origin: species averages.
- Species increases to the direction of the arrow, and decrease to the \S opposite direction.
- The longer the arrow, the stronger the increase.
- Approximation: Project site point onto species vector.

February 17, 2004

Vegetation Analysis

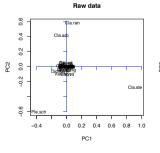

Major ordination methods

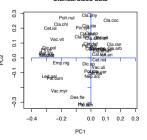

Slide 78

Slide 76

Standardized PCA

Standardizing species to unit variance (using correlation coefficient) makes all species equally important, instead of concentrating on the abundant species with largest variances.

©2002-2004 Jari Oksanen Dept. Biology, Univ. Oulu, Finland

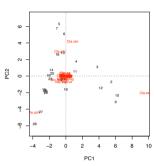

February 17, 2004

©2002-2004 Jari Oksanen

Dept. Biology, Univ. Oulu, Finland

PCA plot

- Axes must have identical scales.
- Origin is special and should be marked: Points near the origin are either average or poorly explained.
- Direction from the origin: The fastest change in species abundances.
- Distance from the origin: The magnitude of change.
- Angles between vectors: Similarity of the response.

Dept. Biology, Univ. Oulu, Finland

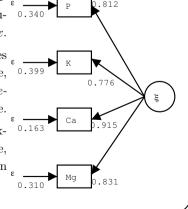

February 17, 2004

Slide 81

Vegetation Analysis Major ordination methods

Confirmatory Factor Analysis

- The real variables ξ are nonobservable (latent), but they influence several observable variables x.
- Select a set of observable variables as indicators of the latent variable, and use them to build a *measure-ment model* for the latent variable.
- The latent variables are truer explanatory variables than single, noisy observed variables and can be used in further modelling.

Vegetation Analysis Major ordination methods

Factor Analysis (FA)

- Factor Analysis instead of PCA in many programs.
- Factor Analysis is a **statistical** method, whereas PCA is only a rotation.
 - World has two components: Common and unique.
 - FA tries to explain only the common component.
 - PCA discards later axes in hope of discarding unique variation, but that is mixed with all axes – kept and rejected.
- Latent variables ξ generate the observed variables x which have unique errors ε .
- Exploratory FA: Rotation to a simple structure.

Major ordination methods Slide 83

Dissimilarities for community data

- Presence/absence indices based on the number common species J on two sites compared to species richness A, B of sites.
- Similarity index s can be transformed to a dissimilarity index d = 1 s.

- 1. **Manhattan style**: use common part of abundance and sums.
- 2. **Euclidean style**: use cross products and sums of squares.

Jaccard: $\frac{J}{A+B-J}$ Sørensen: $\frac{2J}{A+B-J}$

Sørensen: $\frac{1}{A}$ Ochiai: $\frac{1}{A}$

Kulczyński: $\frac{1}{2} \left(\frac{J}{A} + \frac{J}{B} \right)$

February 17, 2004

Vegetation Analysis

Major ordination methods

Slide 85

Metric properties of indices

An index d is a **metric** if:

1. if a = b, then $d_{ab} = 0$

minimum 0

2. if $a \neq b$, then $d_{ab} > 0$

always positive

 $3. \ d_{ab} = d_{ba}$

symmetric

 $4. \ d_{ac} + d_{cb} \ge d_{ab}$

 ${\it triangle\ inequality}$

Semimetric: Does not obey triangle inequality

Vegetation Analysis Major ordination methods Slide 84

The number of indices is a legio

Manhattan style

Euclidean style

$$J = \min_{i} (x_{ij}, x_{ik}) \qquad J = x_{ij} x_{i}$$

$$A, B = x_{ij} \qquad A, B = x_{ij}^{2}$$

Slide 86

Correspondence Analysis (CA)

Invented independently numerous times:

- 1. Correspondence Analysis: Weighted Principal Components with Chi-squared metric.
- 2. **Optimal Scaling:** Find site and species scores so that (i) all species occurring in one site are as similar as possible, but (ii) species of different sites are as different as possible, and (iii) sites are dispersed as widely as possible relative to species scores.
- 3. **Reciprocal Averaging:** Species scores are weighted averages of site scores, and simultaneously, site scores are weighted averages of species scores.

Major ordination methods Slide 87

Chi-squared metric

- Metric is a 'yardstick' to measure dissimilarities among points.
- PCA uses constant ('Euclidean') metric, but CA uses expected abundances as a metric.
- Expected abundances from marginal totals: Exactly like in χ^2 analysis of contingency tables.
- Species profile is the average proportion of species in the data, and site profile is the average proportion of sites.

Euclidean: $d_{ij} = f_{ij} - e_{ij}$

Chi-squared: $\chi_{ij} = (f_{ij} - e_{ij})/\sqrt{e_{ij}}$

©2002-2004 Jari Oksanen

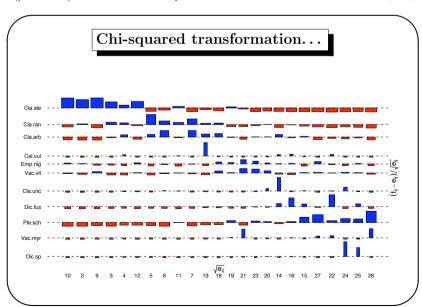

Dept. Biology, Univ. Oulu, Finland

February 17, 2004

Vegetation Analysis

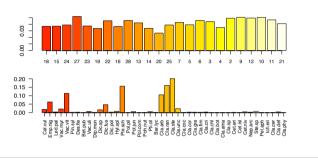

Major ordination methods

Slide 89

Species and site profiles

- All sites should have all species in the same proportions.
- Chi-squared distance is the difference between expected profile and real abundance distributions both for the species and the sites.

Vegetation Analysis Major ordination methods Slide 91 Vegetation Analysis Major ordination methods Slide 92

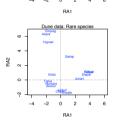

Rare species

Rare species cannot have an average profile and are extreme in CA – but have small weights. Solutions to the "problem":

- 1. Remove rare species.
- 2. Downweight rare species.
- 3. Do not show rare species: Popular.

When scaling is optimal?

- The species optima should be widespread: Measured by between species variance SS_B.
- The species responses should be narrow: Measured by within site variance of species optima SS_W.
- Total variance is $SS_T = SS_B + SS_W$.
- If most variance is between sites, the scaling is optimal.
- The criterion variable $\lambda = SS_B/SS_T$ is maximized in CA.

Suboptimal scaling

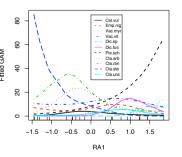

Vegetation Analysis

Major ordination methods

Slide 94

Unimodal response

- Optimal scaling tries to pack Unimodal response species occurrences into tight parcels: model.
- Eigenvalue λ tells the success of packing – but too high a value (~ 1) indicates disjunct subsets of sites.

Major ordination methods

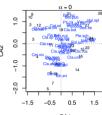

Slide 95

Major ordination methods

Reciprocal weighted avarages

- Repeated application of weighted averaging leads into CA.
- Weighted averages shrink by factor λ and need restoring.
- Species scores can be weighted averages of site scores ($\alpha = 1$), or vice versa ($\alpha = 0$), or restored symmetrically ($\alpha = \frac{1}{2}$).

$$\begin{pmatrix} u_i & = & \lambda^{\alpha-1} - \frac{j}{j} \frac{x_{ij} v_j}{j} \\ v_j & = & \lambda^{-\alpha} - \frac{i}{i} \frac{x_{ij} u_i}{i} \end{pmatrix}$$

Vegetation Analysis

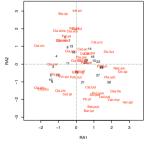

Major ordination methods

Slide 97

CA: Joint plots

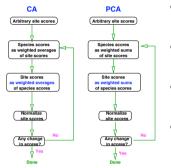

Biplot with weighted Chi-squared metric: Species and sites in the same plot (but scaling α counts).

- Distance from the origin: Chi-squared difference from the profile.
- Points at the origin either average or poorly explained.
- Distant species often rare, close species common.
- Unimodal interpretation: Species optima and gradient values - at least for well explained species.

Power algorithm

Arbitrary vector multiplied with high power of a matrix converges to the eigenvector of the matrix.

- Repeated application of weighted averaging gives CA solution.
- Repeated application of weighted sums gives PCA solution.
- Both methods simple, but numerically poor.
- In fact, CA and PCA both are best made using [weighted] SVD of [Chisquare transformed matrix.

Vegetation Analysis

Major ordination methods

Slide 98

Slide 96

Eigenvalue in CA

- 1. The factor of shrinking in weighted averaging: $\lambda = 0 \dots 1$.
- 2. The proportion between site variation from total variation: $\lambda = 0 \dots 1$.
- Sum of all eigenvalues = mean squared contingency coefficient: The statistic decomposed into linear components in CA.
 - No ecological meaning: "Proportion of 'variance' explained" neither meaningful.
 - Variance is never evaluated in CA.
- Eigenvalues close to 1 suspious: Probably a disjunct subset of points.

©2002-2004 Jari Oksanen Dept. Biology, Univ. Oulu, Finland February 17, 2004

Dept. Biology, Univ. Oulu, Finland

Detrended Correspondence Analysis (DCA)

Mission to correct three 'artefacts' in CA:

- 1. **Detrending** to remove 'spurious' curvature in ordination.
- 2. **Rescaling** to correct shrinking at the ends of ordination axes.
- 3. **Downweighting** to reduce the influence of rare species.

Program Decorana the only implementation – difficult to separate a program from the method.

Vegetation Analysis

Dept. Biology, Univ. Oulu, Finland

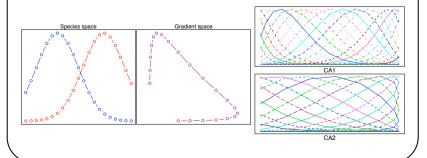

February 17, 2004

Slide 101

The birth of the curve

Major ordination methods

- There is a curve in the species space, and PCA shows it correctly.
- CA may be able to deal with unimodal responses, but if there is one dominant gradient, the second optimal scaling is folded first axis.

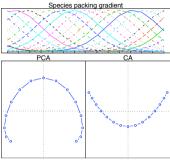

Detrending CA: The argument

Major ordination methods

PCA and CA both produce a curve from a single, ideal gradient, but the shapes have one important difference:

• Horseshoe in PCA curved inwards at ends: Wrong order along the first axis.

• Arc in CA preserves the correct ordering along the first axis: Worth of detrending.

Vegetation Analysis

Major ordination methods

Slide 105

Hill indices of beta diversity

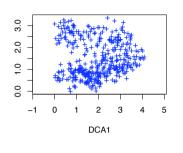

- 1. Average width of species responses.
- 2. Variance of optima of species occurring in one site.
- Used with scaling of ordination axes.
- The first index discussed and described, but the second applied.
- Equal only to degenerated species packing gradients.

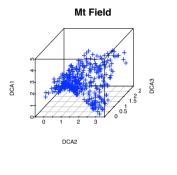

Gaussian responses fitted to species occurring in one site.

Detrending artefacts

- DCA configuration usually a triangle or a diamond: an artefact.
- DCA detrends twisting the space: 'Lollypop' or 'lasagna' effect.

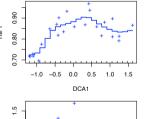

Vegetation Analysis

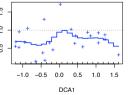

Major ordination methods

Slide 106

Rescaling and downweighting

- Rescale gradients so that the weighted variance of species scores = 1 along $\frac{1}{2}$ the axes.
- Often said that average width of responses is 1 'sd' unit, but that is never done.
- Downweighting: Reduce abundances [™] = of rare species so that they have still less weight on ordination.

©2002-2004 Jari Oksanen Dept. Biology, Univ. Oulu, Finland February 17, 2004

©2002-2004 Jari Oksanen

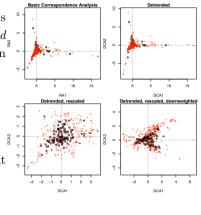

Dept. Biology, Univ. Oulu, Finland

Method or Programme?

It seems that DECORANA rather is a piece of software than a $method_{\frac{3}{2}}$ of ordination, since it is a collectin of three different tricks:

- 1. Detrending
- 2. Rescaling
- 3. Downweighting

Rescaling often is more important than detrending. . .

Vegetation Analysis

Dept. Biology, Univ. Oulu, Finland

February 17, 2004

Slide 109

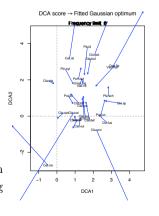

Is DCA based on Gaussian response model?

Major ordination methods

Cajo ter Braak:

"Four conditions (equal tolerances, equal or independent maxima, and equally-spaced or uniformly distributed optima and sample points) are needed to show that (detrended) correspondence analysis provides an approximate solution to the unimodal models." Biometrics 41, p. 870 (1985).

= (D)CA can approximate Gaussian model – if we have infinite species packing gradients.

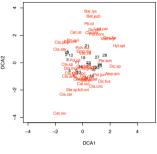

Vegetation Analysis Major ordination methods

DCA plot

DCA plots often taken more seriously than other ordinations:

- Axes taken as gradients, and even scaled in ecologically meaningful 'sd' units.
- Species scores taken as species optima.
- Species scaled so that site scores are their direct weighted averages $(\alpha = 1)$.

Weighted averages are good estimates ...

... of **species optima** if:

- 1. Sites x are evenly distributed about optimum u
- 2. Sites are close to each other

\dots of **gradient values** if:

- 1. Species optima u evenly distributed about site x
- 2. All species have equal response widths t
- 3. All species have equal maximum abundance h
- 4. Optima u are close to each other

Conditions true only for infinite species packing gradients.

Non-metric Multidimensional Scaling (NMDS)

- Rank-order relation with community dissimilarity and ordination distance: No specified form of regression, but the best shape is found from the data.
- Non-linear regression can cope with non-linear species responses of various shapes: Not dependent on Gaussian model.
- Iterative solution: No guarantee of convergence.
- Must be solved separately for each number of dimensions: A
 lower dimensional solutions is not a subset of a higher, but each
 case is solved individually.
- A test winner.

Vegetation Analysis Major ordination methods Slide 113

Monotone regression

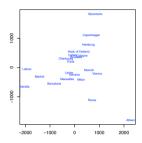

- Measured community dissimilarities and ordination distances have similar rank ordering.
- No specified shape, but can cope with different response shapes.
- Sum of squared residuals from the regression: Stress.
- The model behind: Finds gradients if dissimilarities meaningful.
- Iterative solution: No guaranteed convergence.

Vegetation Analysis Major ordination methods

MDS is a map

- MDS tries to draw a map using distance data.
- MDS tries to find an underlying configuration from dissimilarities.
- Metric MDS (PCoA) assumes linear relation, but NMDS finds any relation.
- \bullet Only the configuration counts:
 - No origin, but only the constellations.
 - No axes or natural directions, but only a framework for points.

Map of Europe from road distances.

Recommended procedure

- 1. Use adequate dissimilarity indices: An adequate index gives a good rank-order relation between community dissimilarity and gradient distance.
- 2. No convergence guaranteed: Start with several random starts and inspect those with lowest stress.
- 3. Satisfied only if minimum stress configurations are similar.

Good dissimilarity measures for gradients

- The Model: Find a a dissimilarity measure that describes correctly gradient separation.
- Bray-Curtis (Steinhaus), Jaccard and Kulczyński.
- 'Wisconsin double standardization' often helpful: First standardize each species to equal maximum, then sites to equal totals.
- Euclidean distance and Chi-squared dissimilarity are poor.

Vegetation Analysis Major ordination methods Slide 117

Comparing configurations: Procrustes rotation

- Procrustes rotation to maximal similarity between two configurations:
 - Translate the origin.
 - Rotate the axes.
 - Deflate or inflate the axis scale.
- Single points can move a lot, although the stress is fairly constant: Especially in large data sets.

Vegetation Analysis Major ordination methods Slide 116

Starting MDS

- Most software packages start with metric MDS (PCoA), but this is dangerous:
 - 1. Metric MDS may be close to a local minimum which traps the iteration.
 - 2. Hides the uncertainty of convergence from the user (and that is unmoral).
- Start with random configurations, and compare minimum stress solutions.

Outliers in the outskirts

- Points that have just a little in common with just a couple of sites are difficult to locate
- $\bullet\,$ Often a marginal circle
- Sometimes a point could be in two alternative locations

Number of dimensions

- In eigenvector methods axes are orthogonal and previous axes remain unchanged when new axes are evaluated.
- MDS Solutions for each number of dimensions separate.
- Adequate number of dimensions difficult to know: After sudden drop of stress is a good idea.

Slide 121

MDS plot

- All that counts is the configuration: Axes are nothing.
- No origin, but just a map.
- Species can be added as their weighted averages.

Scaling of axes

MDS axes have no unique scaling or direction, but all rotations and scalings are equally good solutions.

• Customary to rotate to principal components: First dimension most important.

• Half-change scaling give ecologically meaningful units.
